LONG TERM TILLAGE AND ROTATION TRIAL Merriwagga 1999-2014

the de

FARMERS ADVANCING RESEARCH

VERSIZ

LONG TERM TILLAGE & ROTATION TRIAL

KEY POINTS

* No till treatments have been higher yielding and more profitable in continuous cropping rotations. Cultivation has increased yield and profit in 18 month fallow rotations.

* Two cereals followed by a break crop of either fieldpeas or canola no till has been the most profitable rotation. Interestingly 16 years continuous wheat has not been too far behind.

*Weed spectrum and numbers have changed dramatically within rotations and tillage methods. Interestingly no till treatments have hosted less weeds than cultivated treatments.

*One year of no pre emergent herbicide has taken the trial back 6 years and allowed large numbers of ryegrass to again become established and set seed.

BACKGROUND

The Merriwagga tillage and rotation trial was established in 1999 aimed at comparing no till farming techniques against conventional farming methods over 5 different cropping rotations.

This trial has been managed by local growers and NSW DPI district agronomists Myles Parker and Barry Haskins, and is now managed by Ag Grow Agronomy and research on behalf of Merriwagga growers and our research partner Central West Farming Systems Inc.

During this time this trial has hosted thousands of farmers from across Australia and even the world in a practical learning environment where differences in farming systems can be visually experienced and discussed.

TRIAL DETAILS

The trial is situated approximately 10km west of Merriwagga NSW. Soils are red sandy loams with an underlying calcareous subsoil. They are typically low in organic carbon, pH 5.5-6.5 and have a tendancy to erode with wind and water.

Each plot is 1ha in size, and each treatment is

replicated 3 times. This adds to a total of 30ha.

Tillage teatments

No-till

- all weed control by herbicides or narrow windrow burning
- sown with NDF single disc seeder
- stubble retained where possible

Conventional

- weed control both by herbicides and cultivation
- sown with NDF single disc seeder
- stubble incorporated.

Rotations

Continuous wheat

Rotation 1 and 2 - Two cereals followed by a break crop such as peas or canola.

Wheat - Fallow - Wheat

Wheat - Ley - Fallow - Wheat (note this rotation has simply been Wheat - Fallow - Wheat since 2005, and alternates with the above wheat - fallow - wheat rotation.

Table 1: Rotational history since 2010.

Treatment	Tillage	Rotation

RESULTS AND DISCUSSION

There are many measurements and experiences from this trial. This report will briefly focus on the key outcomes being economic comparisons, nutrition and weeds. There has also been some interesting research on root diseases however this information is not reported in this document.

Economic comparisons

After 16 years there are some very clear trends that have emerged. It is important to note that all costs are calculated at locally validated contract rates. This is very different to the costs a typical farmer would apply, but it allows a very good comparison of the real costs associated with each farming system.

a) No till farming methods have maintained or increased yield in continuous cropping rotations. This is not the case when a fallow is included in the rotation, and in this case cultivation has increased yields in most but not all seasons.

b) When using contract rates, growing crops with no till farming techniques has been on average 15% cheaper than when cultivation is used.

c) The most profitable rotation has been two cereals followed by a break crop of either peas, lupins or canola under a no till system. Interestingly a continuous wheat rotation no till is a close second. Agronomically the continuous wheat rotation has higher risks of crop failure due to higher weed numbers, lower nutrition and subsoil moisture reserves and higher presence of root diseases. This trial has proven however that in this environment this rotation has still performed exceptionally well.

Figure 2: Yield, protein, costs and profit for each Treatment in 2014. Note WLFW was in fallow, hence no yield reported.

		Yield (kg/ha)	Protein (%)	Costs (\$/ha)	Profit (\$/ha)
Continuous wheat	conventional	1458	8.1	\$267.00	\$90.31
	no till	1356	8.2	\$222.00	\$110.10
Rotation 1	conventional	657		\$256.00	\$39.50
	no till	580		\$211.00	\$50.00
Rotation 2	conventional	1490	8.6	\$267.00	\$98.03
	no till	1540	8.7	\$222.00	\$155.38
WFW	conventional	2089	9.7	\$346.72	\$268.61
	no till	2583	9.8	\$269.30	\$363.09
WLFW	conventional			\$78.00	-\$78.00
	no till			\$78.00	-\$78.00

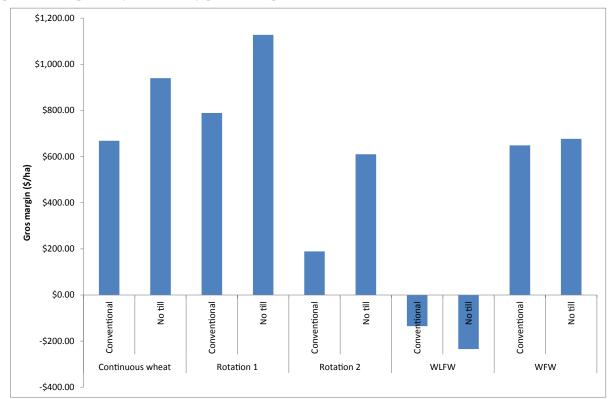

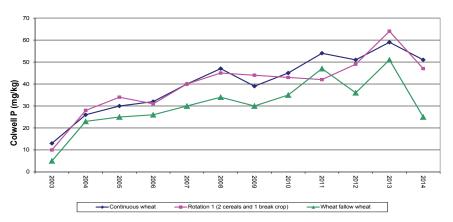

Figure 3: Long term (1999-2014) gross margins for each treatment.

Nutrition

Variation in soil nutrition between no till and cultivated treatments has not been proven. There has however been consistent differences between rotations. In general rotations with a fallow and/or peas have measured significantly higher soil nitrogen status. This is to be expected.

Another interesting trend has been the steady increase in soil colwell phosphorous. This may be due to the fact that during the drought we were adding more phosphorous than we were taking out. This has not been the case since 2010 and yet the trend of inceasing soil phosphorous has continued.

Figure 4: Soil P Curves of each treatment from 2003 to 2014.

Merriwagga CWFS site P levels 2003-2014

Weeds

Differences in weed numbers and weed spectrum have been measured in this trial between rotations and tillage.

In general, no till rotations have hosted less weeds than cultivated rotations. This is thought to be as a result of better herbicide efficacy in no till systems with pre emergent herbicides and also the increased weed persistence through seed burial in cultivated systems.

This trend has been measured through the life of the trial, and has been more noticable in the last 6 years.

It has also been noted that no till tends to favour shallow germinating weeds such as ryegrass, whilst cultivated systems favour weeds such as fumitory, mustards, wild oats etc that like soil stimulation or seed burial for germination.

As expected, rotations with fallows tend to be the cleanest for weeds. Rotations with fieldpeas and lupins often host higher levels of fumitory, a major weed in this trial. Continuous wheat rotations were at a stage where ryegrass was outcompeting the crop by 2007, however well planned pre emergent herbicide strategies reduced ryegrass levels where they were not that different to other rotations, until 2014.

In 2014, the trial was sown without a pre emergent herbicide. This was done for research purposes and was a major mistake, as even though the trial had been clean for atleast 4-5 years, the seed bank was still obviously high enough to create a massive growth of weeds, in particular ryegrass. No post emergent herbicide options work at this site for ryegrass.

Figure 5: Weed counts for each treatment measured before post emergent herbicides were applied in 2014, and a final score of ryegrass weediness at the end of the season.

		Aver	Average Weeds per treatment (weeds/m2) June 6th							
								end of season (0-

ACKNOWLEDGEMENTS

Ag Grow Agronomy and Research and Central West Farming Systems would like to acknowledge Ian Barber "Sylvanham" for undertaking various activities such as sowing and harvesting the trial, as well as other local farmers in their efforts to help make this trial what it is.

Also we would like to thank David Coddington and Pioneer Dupont for their continued support by providing a weighbin at harvest.
